Array Operations: Maximum Priced Fruit

There are ***N*** different types of fruits available in the market.
You are given the ***name*** and ***price (P)*** of ***N*** fruits.

Write a program to find the name and price of the fruit with the maximum price.

Note
There are all unique fruits at a unique price.
Hence, there is only one maximum price.

Function Description
In the provided code snippet, implement the provided `fruitPrice(...)` method using the variables to print the name and price of the fruit with the maximum price. You can write your code in the space below the phrase `"WRITE YOUR LOGIC HERE".`

There will be multiple test cases running, so the Input and Output should match exactly as provided.
The base Output variable `result` is set to a default value of `-404` which can be modified. Additionally, you can add or remove these output variables.

Input Format
The first line contains ***N***, denoting the number of fruits.
The next ***N*** lines contain the name and price of each fruit.

Sample Input

```
3               -- denotes the number of fruits
orange 10       -- denotes the names and price of each fruit
apple 30
banana 20
```

Constraints
1 <= ***N*** <= 100
1 <= ***P*** <= 1000 (range of price of fruits is per pound)

Output Format
The output contains the name and price of the fruit with the maximum price separated by a space.

Sample Output

```
apple 30
```

Explanation
The price of an apple is 30, which is greater than the price of orange and banana.
Hence, the output is ***apple 30***.
